## Conclusions

Results and recommendations

# 01

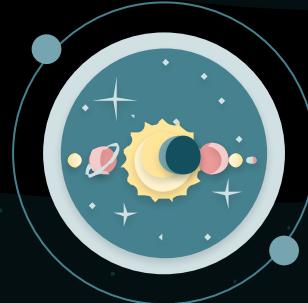

# Problem Statement

Can satellite imagery be  
used to predict poverty in US  
cities?

We will look at DC and  
Chicago satellite imagery to  
find out...

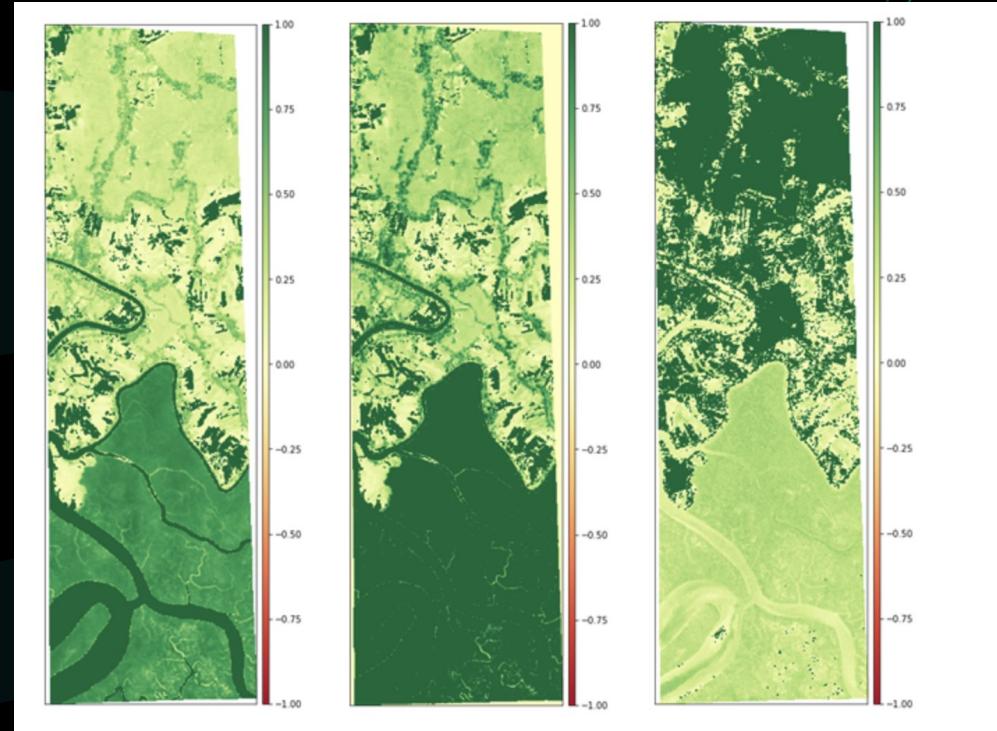

# Why?

- Census only once every 10 years
- Hard to capture people without permanent addresses
- Does poverty look different in different cities?

# Background on satellite imagery: Nightlights

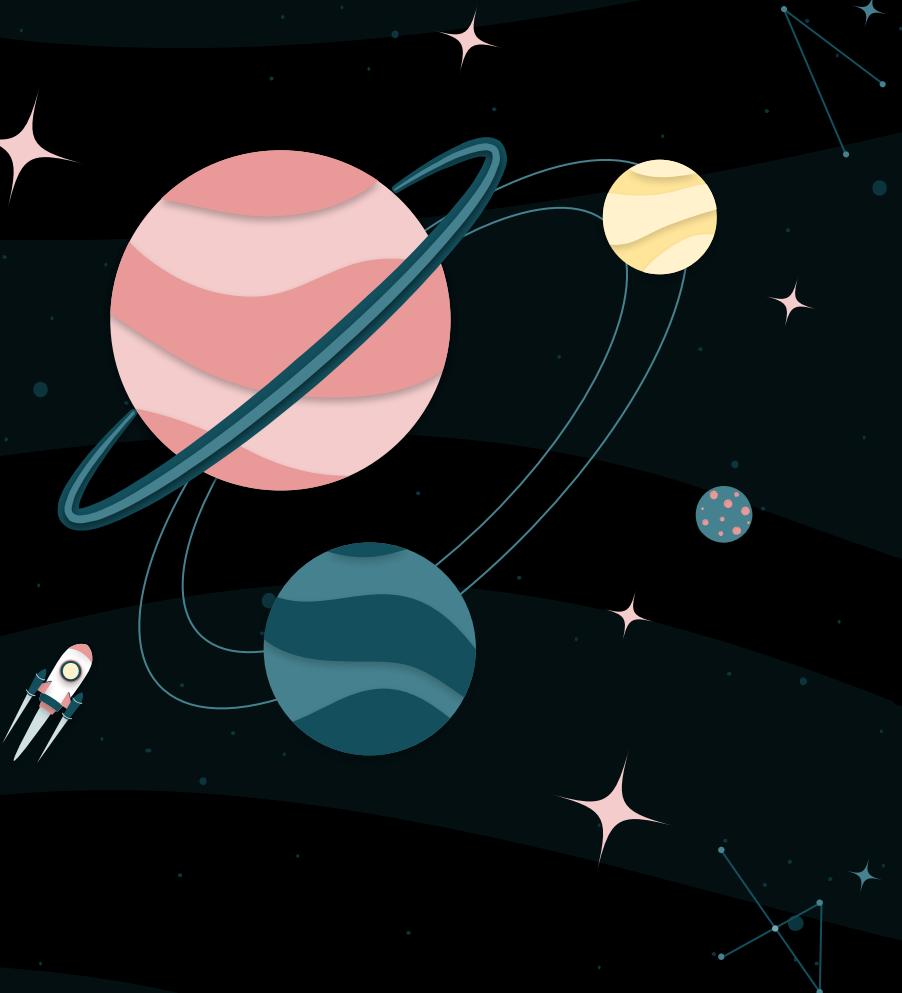

# Background on satellite imagery: Agriculture

- Three different ways of calculating sunlight reflected by plants, from [this blog](#)

02

# Acquiring the Data

# Sources

## Google Earth

Used to acquire both DC and Chicago imagery

## Censusapi

Income data for each census block group

## Data Portals

Each city had data portals to download shapefiles

# New Libraries

## Geopandas

Allows coders to work with shapefiles and polygons

## Rasterio

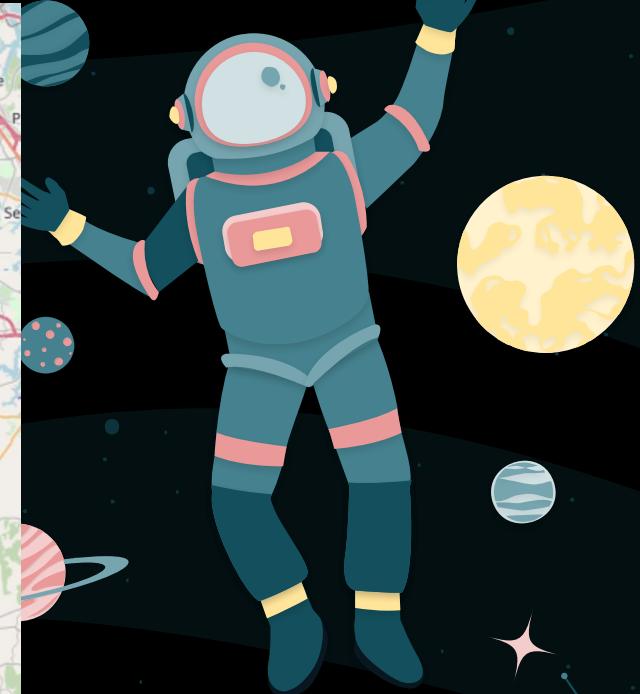

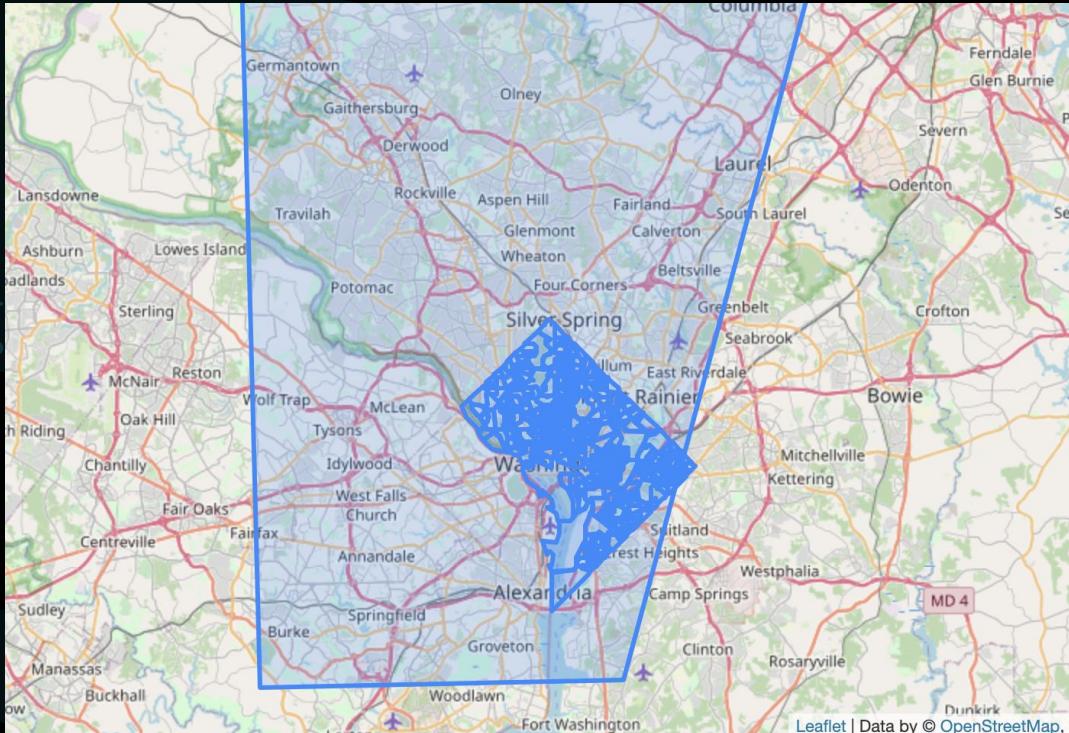

Allows coders to work with imagery - like pictures but with many more spectral bands and geographic metadata

# Sentinel 2

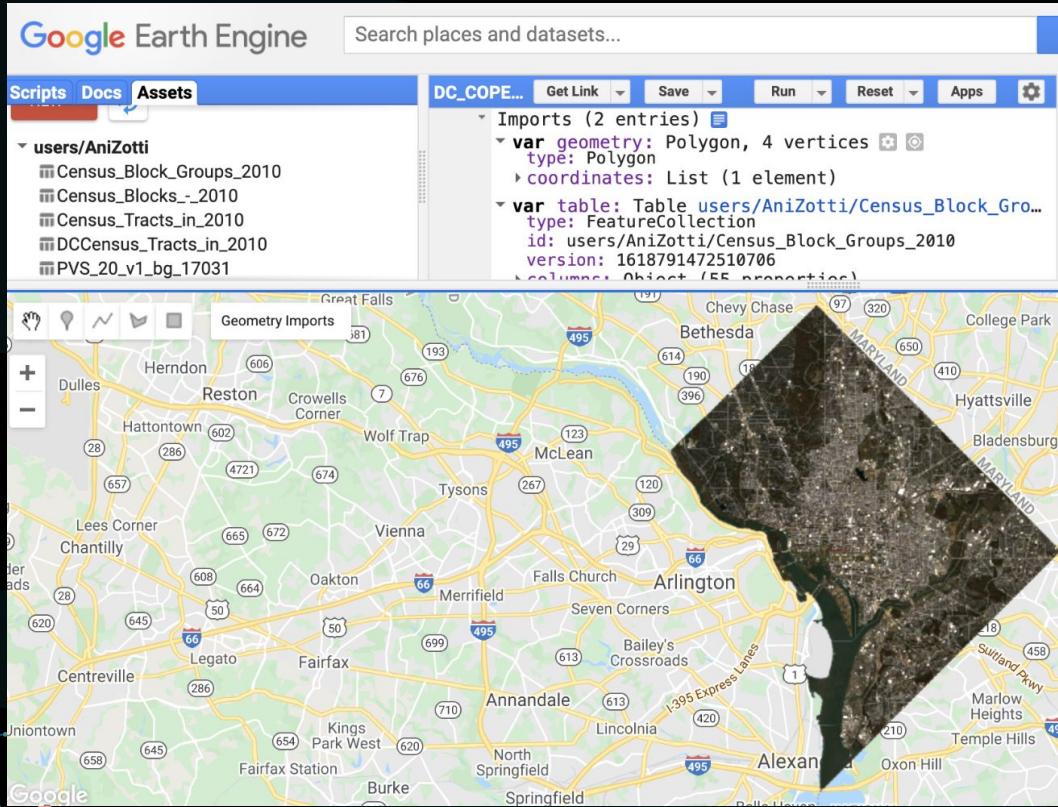

- European Space Agency
- Actually 2 different satellites
- Circles the Earth once every 5 days between the two
- 10m resolution
- 13 spectral bands

# Attempt 1: regularly plotting GIS data is important!

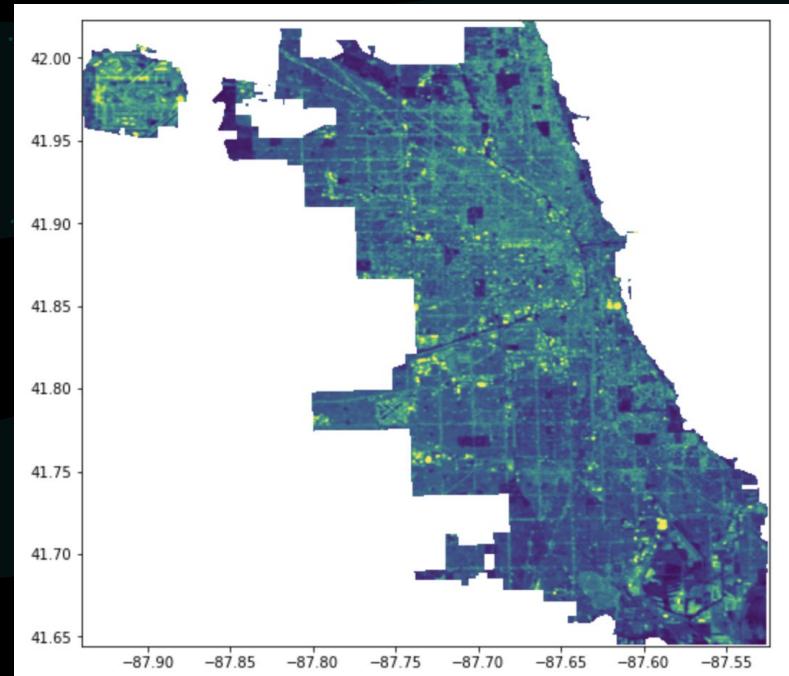

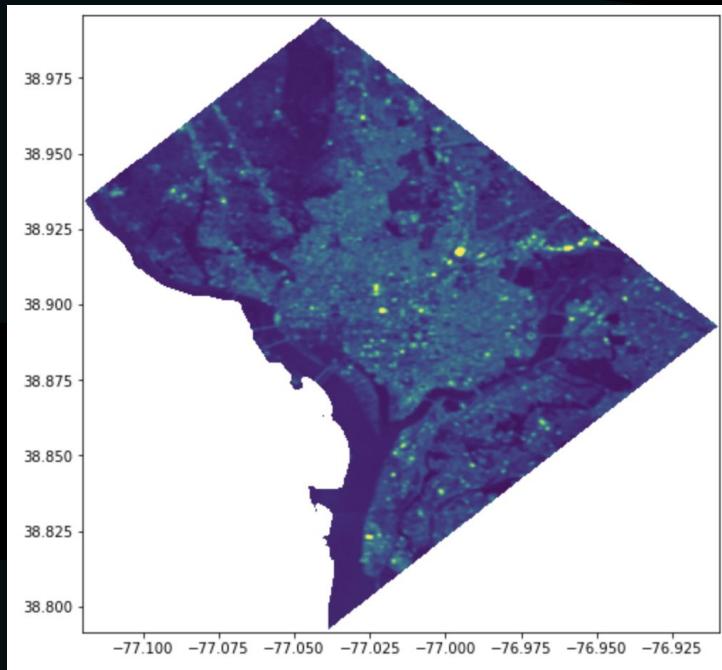

# Google Earth Engine

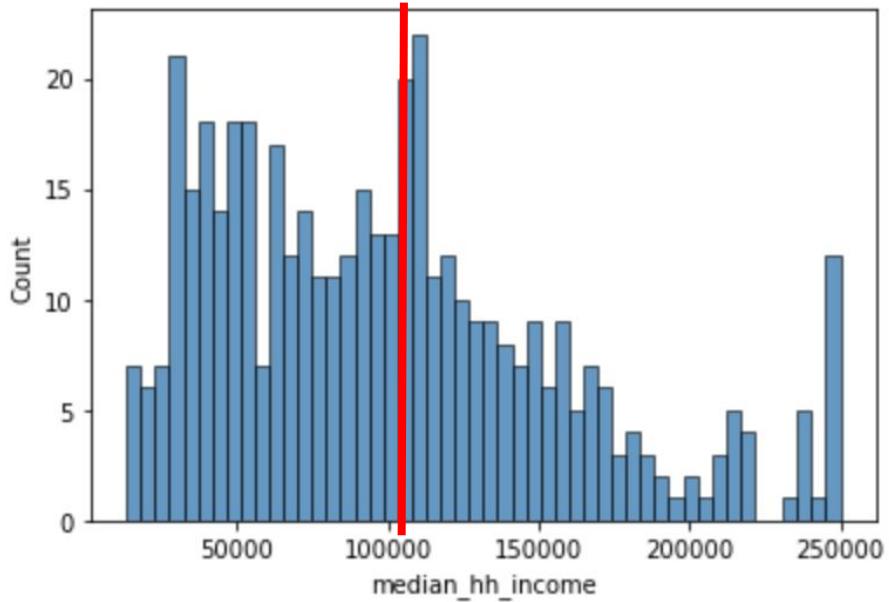

- Building a cloud mask
- Taking the median value for each pixel across each spectral band over a specific timeframe
- Clipping the image by a certain geometric boundary
- Exporting the image to Google Drive

# Imagery in Jupyter

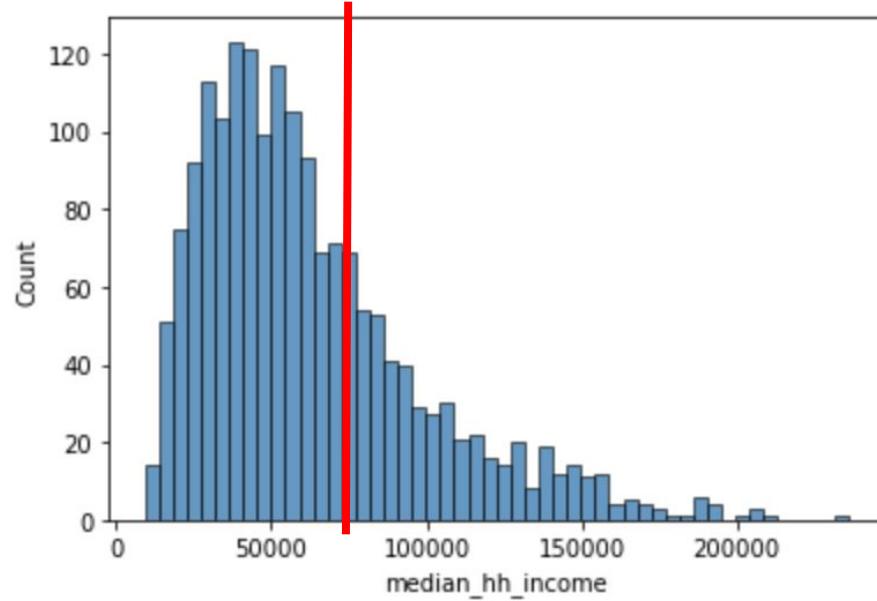

# Income Distribution

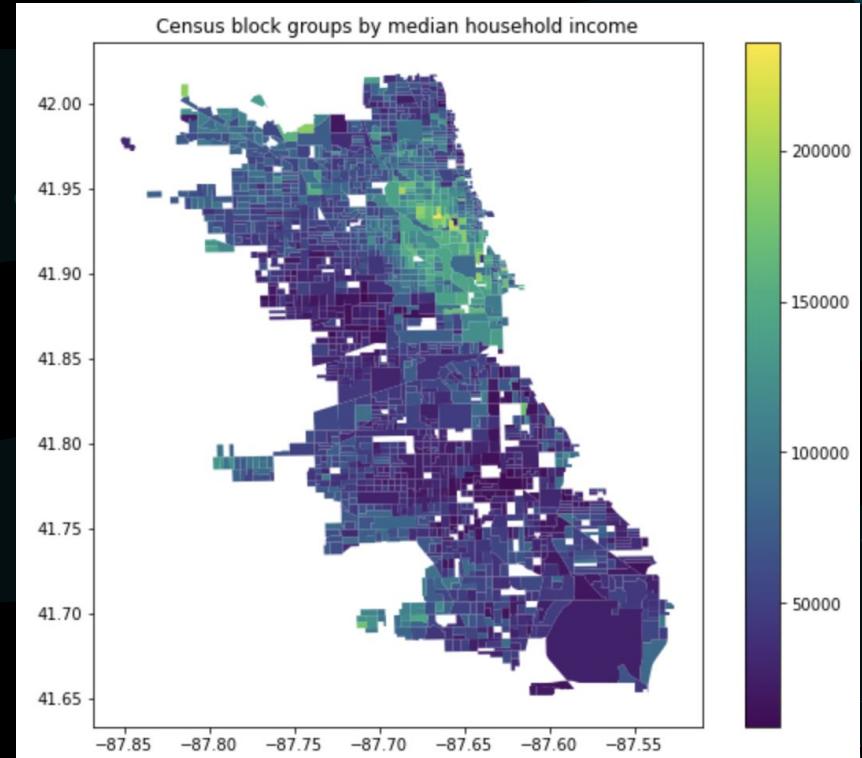

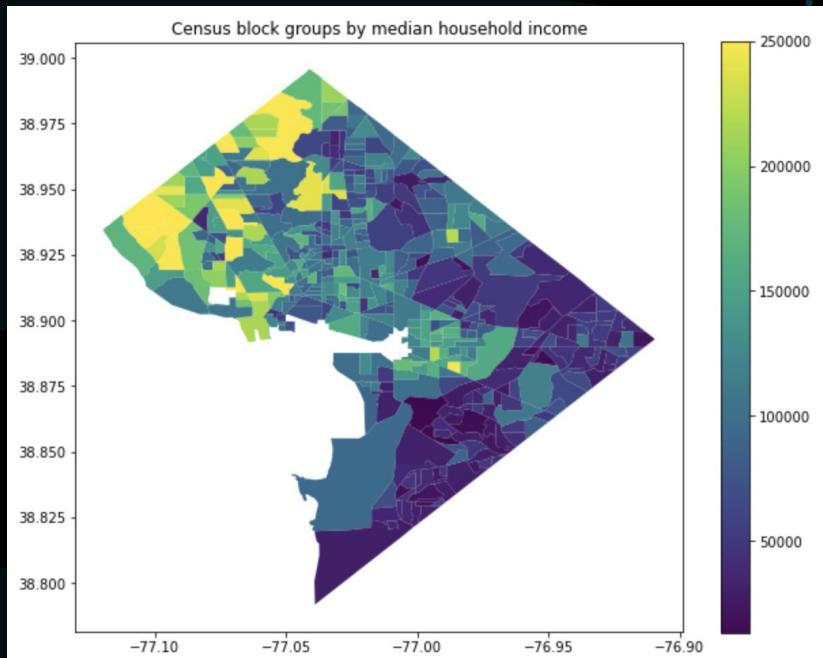

DC

## Chicago

# Imagery in Jupyter

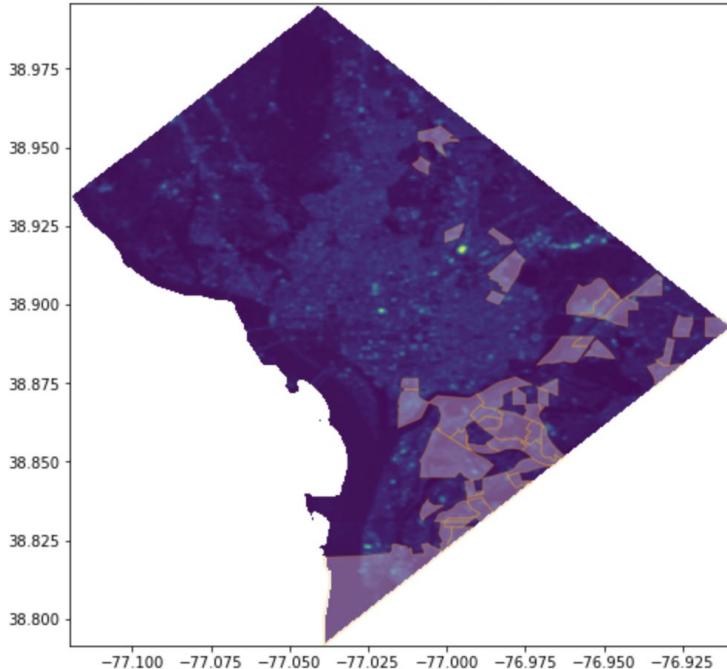

# Poverty

- **Federal Poverty Level for a Family of Four: 26,500**
- **DC's Cost of Living over the National Average: 39%**
- **Chicago's Cost of Living over the National Average: 23%**

# Pulling everything together

DC

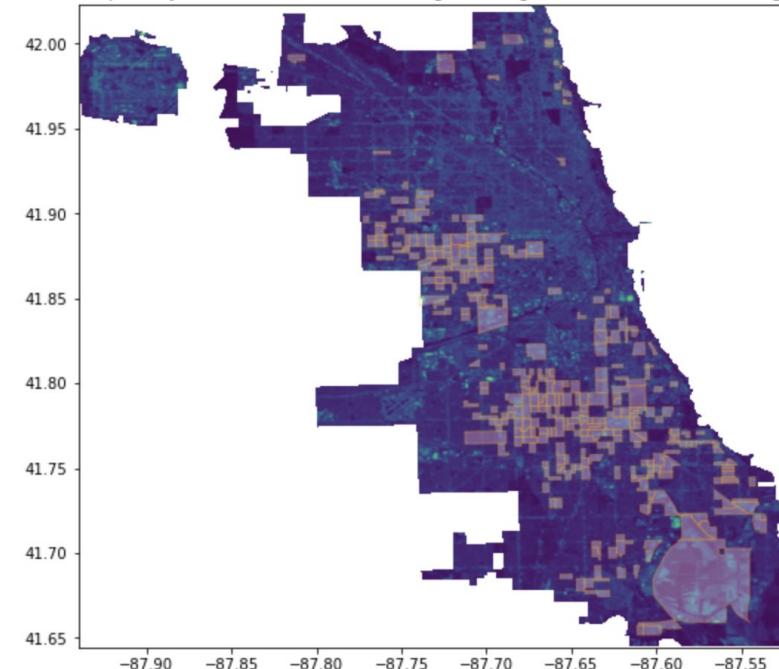

DC Census Block Groups with Median Household Incomes below the Federal Poverty Line, multiplied by DC's Increased Cost of Living (39% higher than the national average)

Baseline: 94%

Chicago

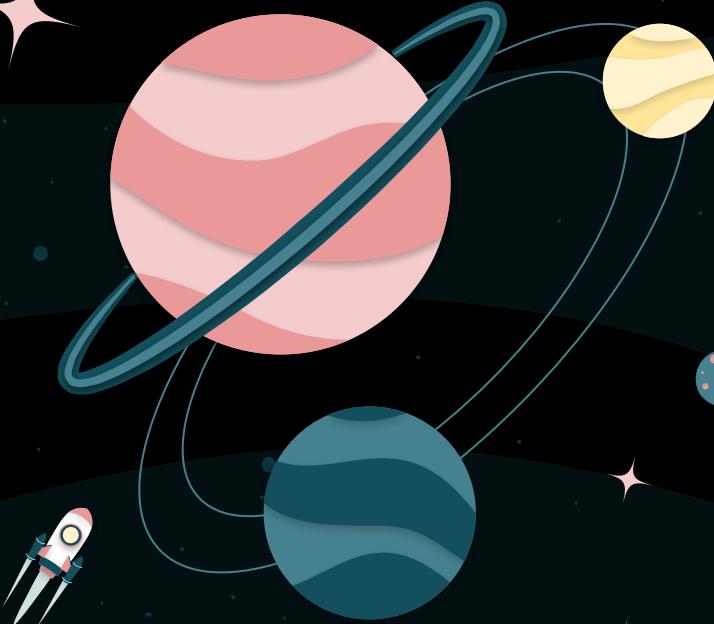

Chicago Census Block Groups with Median Household Incomes below the Federal Poverty Line, multiplied by DC's Increased Cost of Living (23% higher than the national average)

Baseline: 93%

03

# Modeling

# Preprocessing: “Rasterizing” the polygons

DC

Chicago

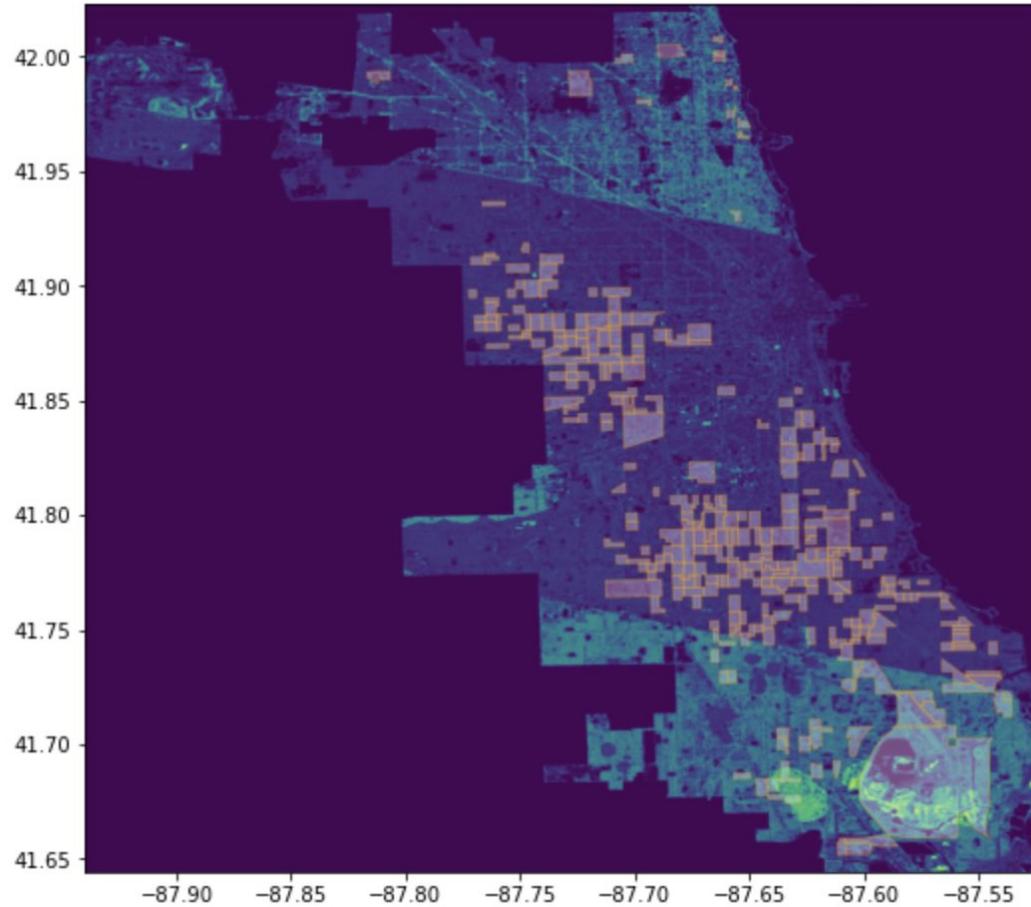

# The models

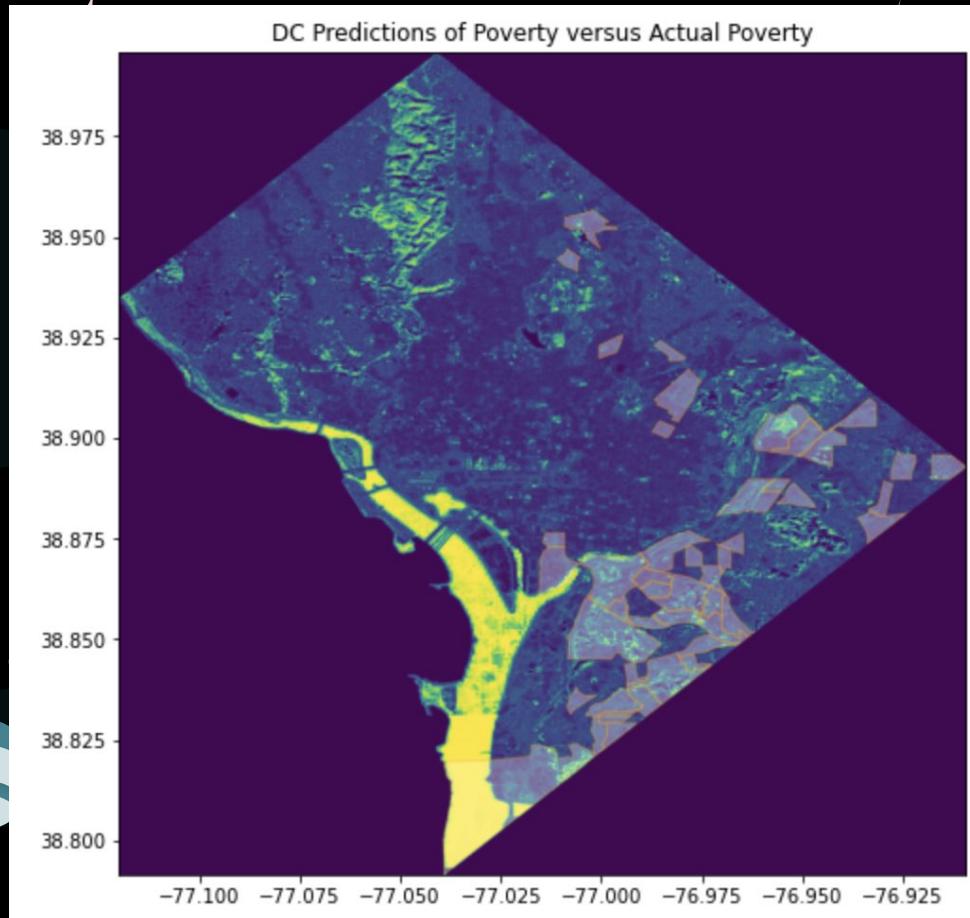

| Models  | Baseline Accuracy* | Precision*  | Recall*      | Accuracy*     | New city?   |
|---|--------------------|-------------|--------------|---------------|---|
| Training on DC data, predicting Chicago poverty             | <b>0.943</b>       | <b>0.68</b> | <b>0.31</b>  | <b>0.953</b>  |  |
| Training on DC data with artificially balanced classes      | <b>0.943</b>       | <b>0.14</b> | <b>0.16</b>  | <b>0.89</b>   |  |
| Training on Chicago data, predicting DC poverty             | <b>0.930</b>       | <b>0.77</b> | <b>0.057</b> | <b>0.9348</b> |  |
| Training on Chicago data with artificially balanced classes | <b>0.930</b>       | <b>0.34</b> | <b>0.58</b>  | <b>0.893</b>  |  |

# Results

Chicago Predictions of Poverty versus Actual Poverty

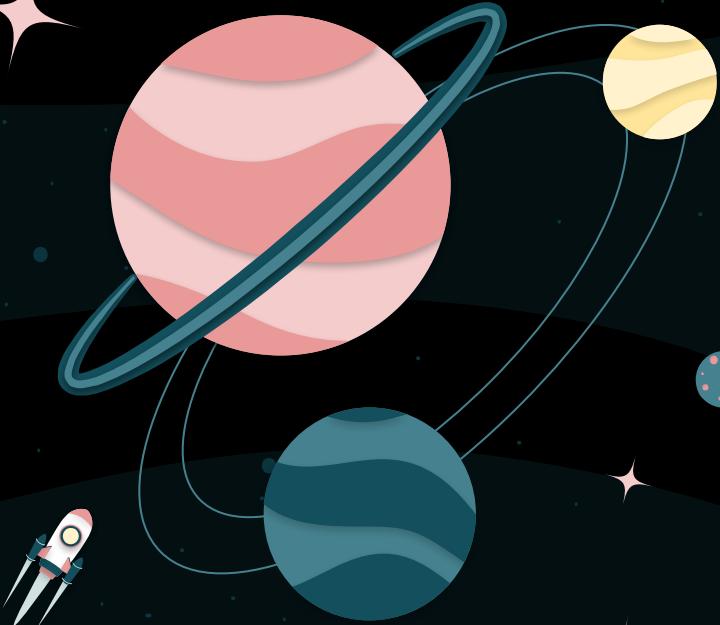

# Other Results

04

# Conclusions

# Recommendations

More data

Thousands of satellite images

More labels

Open Data Portals have shapefiles for buildings, parks, etc

More compute

Required if using more raster files

# Takeaways

Workflow

A success!

Accuracy

Needs work

Different cities

Potentially!
